Working Paper of Portsmouth-Brawijaya Centre for Global Health, Population, and Policy

Number 7

### **Abstract**

Violence against women is a global issue with estimates indicating that 35% of all women world-wide have experienced either physical and/or sexual intimate partner violence or non-partner violence in their life time. In Malawi 42% of ever-married women have experienced some form of violence perpetrated by their current or most recent spouse. A number of studies have investigated intimate partner violence in Malawi within the context of HIV/AIDS and girls sexual abuse and a few have explored the role of socio-cultural factors in influencing gender based violence. No study has used cluster analysis to systematically analyse the groups affected domestic violence across different dimensions of abuse. Using the 2015 Malawi Demographic and Health Survey data, we employed cluster analysis and multinomial logistic regression to analyse the distribution of different forms of abuse amongst married women in Malawi and the key attributes associated with each form of abuse. We find that correlates of domestic violence significantly differ by the following levels of abuse; controlling behaviour, general controlling behaviour, moderate physical and emotional abuse and the high and complete abuse. Alcohol consumption, ethnicity and women working status were significantly associated with all four levels of abuse but age and religion were only associated with controlling behaviour and generalised controlling behaviour. The strength of association between husband's alcohol consumption, woman's working status and marriage type and domestic violence increased by level of abuse. On each of these factors, the odds of experiencing violence were lowest in the controlling behaviour group and highest in the high physical and emotional abuse group.

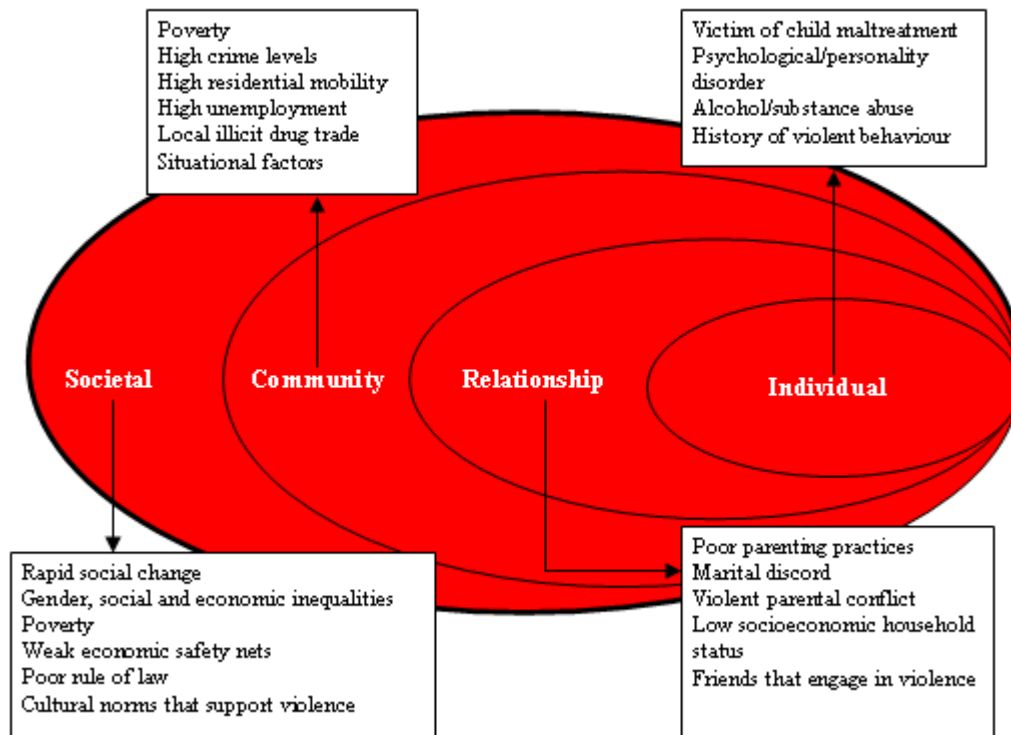

policies and programmes that are designed to tackle violence against married women in Malawi should incorporate strategies that discourage excessive drinking, promote messages that women can be bread winners and discourage polygamous marriage.

The WHO estimates that 35% of all women world-wide have experienced either physical and/or sexual intimate partner violence or non-partner violence in their life time (WHO, 2017). As many as 19% of women in 87 countries surveyed between 2005 and 2016 globally reported experiencing physical and sexual violence in the 12 months prior to the survey (United-Nations, 2018). In Malawi, the most recent Malawi Demographic and Health Survey report estimates that 42% of ever-married women have experienced some form of physical, sexual or emotional violence perpetrated by their current or most recent spouse(NSO-Malawi & DHS-Program, 2017). Sustainable development goal number 5 aims to achieve gender equality and empower all women and girls through various ways including the elimination of all forms of violence against all women and girls in the public and private spheres including trafficking and sexual and other types of exploitation(United-Nations, 2018). Efforts to tackle the problem of violence against women globally through advocacy, empowerment counselling interventions and home visitation appear promising in general but not many countries have made significant strides in reducing violence against women(WHO, 2017). In Malawi there is concordance between men and women in their perception that women do not have the right to refuse to have sex with their husbands and acceptance of intimate partner violence is both a barrier to its reduction and a strong predictor of prevalence(Andersson, Ho-Foster, Mitchell, Scheepers, & Goldstein, 2007; Shwachman Kaminaga, 2017).

There are many theories designed to explain, predict and better understand the causes of domestic violence. The feminist theory is considered a dominant model because it can be applied across cultures, contains both an explanation and a solution and emanates from the discipline of sociology with many feminist scholars(Gelles, 2005). It postulates that violence against women is a result of the inferior position occupied by women in the social structure inherited from a traditional family system and marital violence emanates from inequalities that exist in marriage relationships(Renzetti, Edleson, & Bergen, 2001). Feminists conceptualise all violence as a reflection of the unequal power relationships that exist in society and personal relationships between men and women(Sharma, 1997). However, a more thorough understanding of factors that influence domestic violence can be achieved by using the ecological framework (figure 1). Carlson(1984) adapted Urie Bronfenbrenner's ecological model of human development to the problem of domestic violence. The ecological model of domestic violence allows for an analysis of factors at different levels; individual, family, community, society which may operate simultaneously, independently and interactively to influence the emanation and persistence of domestic violence. The WHO Violence Prevention Alliance uses the ecological framework to guide its understanding, undertake research and implement actions for violence prevention(WHO, 2018). This framework illustrates the factors that may influence violence at

society and community level, within relationships and what makes individuals become perpetrators of domestic violence.

Figure 1: *The ecological framework: examples of risk factors at each level*

Source: WHO(2018) The VPA approach

<http://www.who.int/violenceprevention/approach/ecology/en/>

The interplay of factors shown in the ecological framework has attracted a significant amount of research on domestic violence across the globe. The evidence indicates that although in general the findings are aligned to the ecological framework, there are variations in the relative importance of factors responsible for domestic violence which may be attributed to differences in context, data and research methods. A number of studies have established that the risk of abuse is highest amongst women that are poor and unemployed which may be linked to the resource theory, dependency relations theory, patriarchy theory and feminist theory (Dobash & Dobash, 1979; Gelles, 2005; Hyde-Nolan & Juliao, 2011; Jewkes, 2002; Strauss, Gelles, & Steinmetz, 1980; Warner, Lee, & Lee, 1986). The resource theory presupposes that family members with more resources traditionally command higher power and assure obedience and compliance while those with less resources use violence to maintain power (K. L. Anderson, 1997; Pallikadavath & Bradley, 2018; Warner et al., 1986). The

dependency relations theory proposes that victims of abuse are often dependent on their abuser while patriarchy theory explains that the economic and social processes that operate directly and indirectly to support the patriarchal order lead to the subordination of women which is responsible for violence against women (Alio et al., 2011; Dobash & Dobash, 1979; Hyde-Nolan & Juliao, 2011; NSO-Malawi & DHS-Program, 2017). Interestingly a national cross-sectional household survey in eight countries found that poverty, overcrowding and education were less influential than socio-cultural factors such as multiple partners, attitudes and subjective norms (K. L. Anderson, 1997). Key socio-cultural factors associated with domestic violence in Malawi include forced marriage, dowry practice, polygamy and the notion of household head (Bisika, 2008). Polygamy is common in communities that practice bride price. The presence of co-wife has been linked to domestic violence in several African countries and in Malawi (Alio et al., 2011; Bisika, 2008).

Based on a literature review on gender based violence to inform national response in Malawi, a number of studies have investigated intimate partner violence within the context of HIV/AIDS and girls sexual abuse and a few have studied the role of socio-cultural factors in influencing gender based violence (Mellish, Settergren, & Sapuwa, 2015). However, no study has considered multiple ways in which abuse is perpetrated, nor attempted to analyse the patterns of abuse holistically. Using cluster analysis and multinomial logistic regression, this study identifies the distribution of different forms of abuse amongst married women in Malawi and the key attributes associated with each form of abuse. The study investigates further factors that have been previously linked to domestic violence using the most recent Malawi Demographic and Health survey report providing key information to help government and donor institutions make well informed policy decisions in tackling violence against women in Malawi and populations of similar attributes in other countries.

## **Data**

The data are drawn from the 2015 Malawi Demographic and Health Survey (2015 MDHS) carried out under the DHS programme. The USAID funds the DHS programme in many developing countries. In the 2015 MDHS, ICF International provided technical assistance throughout the study. The sample was selected based on the 2008 Malawi Population and Housing Census frame. Standard enumeration areas were selected based on probability proportional to size. Thirty households were picked from each

enumeration area to make a sample size of 27,516 households. The woman’s questionnaire collected information from 24,562 women out of 25,146 women aged 15 to 49 years that were eligible for the interview representing a 98% response rate. One third of the sampled households received domestic violence questions (6,379 household). Specifically constructed weights were used to adjust for selection of only one woman per household to ensure national representativeness. The domestic violence module collected data on different types of violence; physical, sexual and emotional and level of marital control by husband. The survey also provided information on background characteristics including household wealth status and demographic characteristics of all household members such as age, sex and relationship to household head. Sample weights were included to adjust for differences in the final probability of selection at household level. Further details of study design and data collection are reported on the National Statistical Office of Malawi website: <http://www.nsomalawi.mw/>.

## Methods

### *Explanatory Variables*

The choice of explanatory variables is guided by findings from previous literature, the ecological framework (figure 1) and data availability. The explanatory variables that were explored are described in Table 2. This comprises of demographic variables: age of the woman, age of the woman at first sex, age at first cohabitation, geographic/location variables :urban/rural residence, region, religion, ethnicity and socio-economic variables: household wealth status, whether husband takes alcohol or not, woman’s education level, whether the woman is currently working or not and type of marriage (polygamous or monogamous)).

Table 2 Distribution of variables explored in this study.

<b>Demographic factors</b>	Variable	Frequency	Percentage
Age	15-19	353	7.69
	20-29	2,118	46.15
	30-39	1,461	31.84
	40-49	657	14.32
Age at first sex	Less than 13 years	386	8.39
	14 to 17 years	2,658	57.92
	18 years or over	1,546	33.69
Age at first cohabitation/marriage	Less than 15 years	540	11.77

Polygamous marriage	Yes	588	12.81
	No	4,001	87.19

### ***Statistical Analysis***

#### *Cluster analysis*

Cluster analysis is used to extract meaningful groupings of the experience of domestic violence from the MDHS. 18 binary variables are used in forming clusters, each taking the form of a 0/1 indicator variable where the variable takes the value 1 if the woman reports experiencing that form of domestic abuse and zero otherwise. We include three domains of domestic abuse: physical (formed using reports of the woman being: pushed, slapped, punched, kicked, strangled, threatened with a weapon, limb twisted), sexual (physically forced into sex, coerced into sex, forced to perform a sex act) and controlling behaviour (husband exhibits jealous behaviour, accused of being unfaithful, needs

<sup>1</sup> Christians are comprised of the following denominations: catholics, Central Church of African Presbyterians (CCAP), Seventh Day Adventists, Anglican (aka Church of England) and Pentecostals.

permission to see friends, needs permission to see family, needs to justify whereabouts, humiliated, threatened, insulted). Cluster analysis is performed using the cluster function in Stata 13.0 for Windows (Statacorp, Tx, USA). Clustering is performed using hierarchical cluster analysis based on Ward's distance. To decide on the number of clusters, we use a combination of indices which indicate optimal clustering pattern ( Calinski–Harabasz pseudo-F index (Calinski & Harabasz, 1974) and the Duda–Hart index (Duda & Hart, 1973) and dendritic analysis.

### *Regression analysis*

Once the final cluster profile was selected, membership of a particular cluster was then used as the dependent variable in a multinomial logistic regression. A multinomial logistic regression model is appropriate because instead of running four separate regression models, separate logistic regression model for each indicator variable are estimated simultaneously.

The model takes the form of equation 1

$$\ln\left(\frac{\pi^s}{\pi^{s=0}}\right) = \beta'x$$

$$s = 0 \dots S$$

In equation 1 the probability of belonging to cluster  $s$  is denoted as  $\pi^s$  where there are  $S$  clusters. The probability of belonging to cluster  $S$  is modelled as a logit function of a combination of a vector of coefficients  $\beta$  and associated predictor variables in the vector  $x$ .  $S - 1$  logits are estimated and the baseline cluster  $s = 0$  is omitted to identify the model. (C. J. Anderson & Rutkowski, 2008).

## **Results**

### *Cluster analysis*

Five distinct clusters of abuse were extracted based on a combination of fit statistics and dendritic analysis. Out of the 6,379 households that responded to the domestic violence questions data on type of abuse was available for 4,569 women.

The profile of domestic abuse is presented in figure 2. The first cluster is termed no abuse (NA), and contains women who reported no experience of abuse on any of the response variables. This cluster comprises 25.39% of the sample.

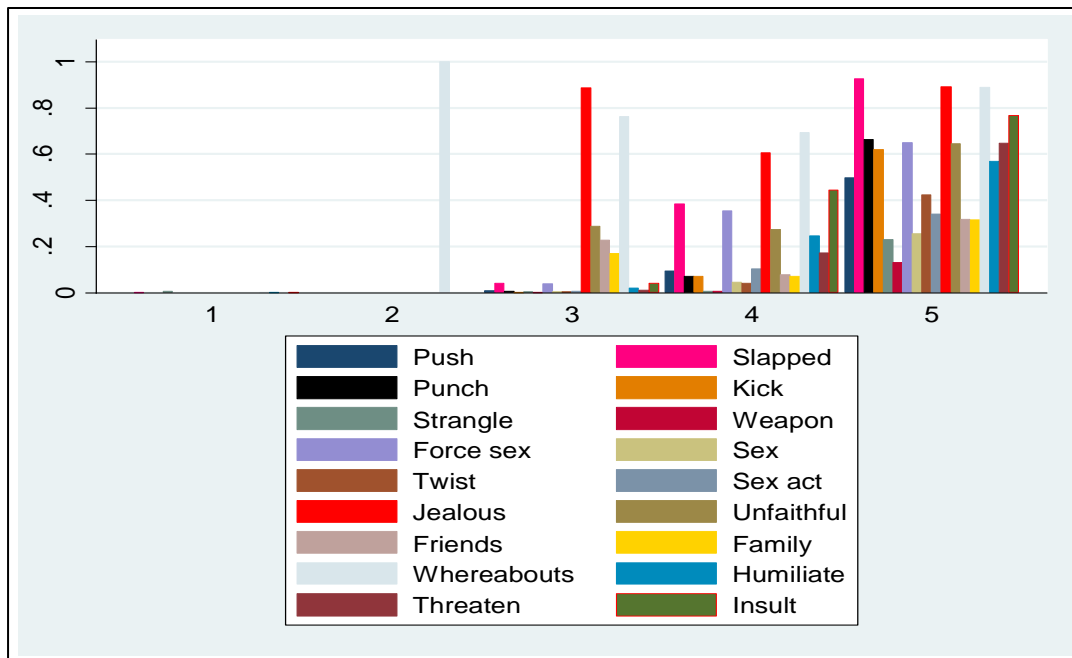

The second cluster extracted is characterised by Controlling Behaviour (CB). All women within this cluster report that they have experienced their spouse demanding knowledge of their whereabouts, but no other form of abuse is present. This cluster comprises 541 women, or 11.79% of the sample.

The third cluster comprises general controlling behaviour (GCB). Women in this cluster experience high rates of jealousy from their husbands (84%) and their husbands demand to know whereabouts (77%), as well as lower level of accusations of being unfaithful (30%), isolation from friends (22%) and family (17%). All indicators of physical abuse are low (below 5%). This is the second largest cluster in the sample comprising 1245 women (27.13%).

Cluster 4 comprises moderate physical and emotional abuse (MPE). Emotional abuse is common in this cluster, with high rates of jealous behaviour (60%) and control of whereabouts (67%). A substantial minority of women in this cluster have experienced physical abuse largely in the form of being slapped (39%) and being forced to perform a sex act (37%). This cluster is the largest in the sample with 1250 women (27.24% of the sample).

Cluster 5 represents the highest overall level of abuse, and is termed the high and complete abuse (HCA). Nearly all women in this cluster have experience some form of physical abuse, with particular high rates of being slapped (90%), punched (65%) and kicked (60%). Women in this cluster also report high rates of forced sex (65%). Controlling behaviour and emotional abuse is also common in this cluster, particularly jealous behaviour (90%), knowledge about whereabouts (90%) being humiliated (55%), threatened (65%) or insulted (75%). This cluster comprises 288 women and is 8.46% of the sample.

Figure 2: Experience of forms of domestic abuse by form of abuse for each cluster

## Exploratory Analysis

Bivariate analysis was undertaken through a chi square test of the association between severity of domestic violence and demographic, geographic and socio-economic characteristics. Age, age at first sex, region, religion, household wealth status, education level, working status, marriage type, whether husband drinks alcohol or not and ethnicity were significantly associated with severity of domestic violence, but there was no association between severity of domestic violence and age difference of husband and wife, age at first cohabitation/marriage and whether the woman is resident in urban or rural. See Table 3.

Table 3 Percentage of women by severity of domestic violence by demographic, geographical and socio-economic characteristics

### Multinomial logistic regression results

Results of the multinomial regression are presented in Table 4. The odds of a woman encountering a particular profile of domestic violence are presented under each column; controlling behaviour, generalised controlling behaviour, moderate physical and emotional abuse and high and complete abuse compared the base category of No abuse. Statistically significant results are in bold.

#### *Controlling behaviour*

The odds of a woman encountering controlling behaviour are 35% lower for women aged 20 to 29 and 36% lower for those aged 30 to 39 compared to those aged 15 to 19. Women from the central region had 69% higher odds of experiencing controlling behaviour compared to women from the northern region. Christian women are also less likely to encounter controlling behaviour compared muslim women, their odds are 39% lower than that of muslim women. Women of Yao and Ngoni ethnicity are less likely to encounter controlling behaviour than women of Chewa ethnicity. Interestingly more well off women are more likely to encounter controlling behaviour than the

poorest (45% more likely for the poorer and middle categories and 78% more likely for those in the richest category. Similarly, women that reported to be currently working were more likely to have encountered controlling behaviour from their husbands than women that were not currently working. The highest difference in the odds of encountering controlling behaviour was between women whose husbands drink alcohol and those that do not. Women who reported that their husbands drink alcohol had 80% higher odds of encountering controlling behaviour compared to women whose husbands do not drink alcohol.

#### *Generalised controlling behaviour*

The odds of women encountering generalised controlling behaviour are also lower for older women compared to the youngest age group (15 to 19 years). The association is only statistically significant amongst the oldest group (40 to 49 years). Women aged between 40 to 49 years have 41% lower odds of encountering controlling behaviour compared to women aged 15 to 19 years. Christian women have 46% lower odds of encountering this form of domestic violence compared to muslim women. Compared to Chewa women, the odds of encountering this form of domestic violence are 40% higher for Lomwe women, 34% lower for Yao women and 37% for Ngoni women. Women that are in the poorest group of the household wealth status variable are more likely to encounter this form of domestic violence compared to women in the poorest category, the odds are 31% higher. Women whose husbands drink alcohol were twice as likely to experience this form of domestic violence compared to women whose husbands do not drink alcohol. The odds of suffering generalised controlling behaviour were 31% higher for women that reported to be currently working than women that were not working and 58% higher for women in a polygamous marriage than those in a monogamous marriage.

#### *Moderate physical and emotional abuse*

There was no significant association between age, region, religion and this profile of domestic violence. A statistically significant association was obtained between this form of domestic violence and the following factors: ethnicity, education level, whether the husband drinks alcohol or not, education level, women's working status and type of marriage. The odds of experiencing this form of domestic violence were 26% lower for Ngoni women than Chewa women, over three times higher for women who reported that their husbands drink alcohol than women who reported that their husbands do not drink alcohol, 34% higher for women with primary education than those with no

education, 36% higher for currently working women than those not working and 76% higher for women in polygamous marriage than those in monogamous marriage.

*High and complete abuse*

Factors that emerged as significantly associated with high and complete abuse were age at first sex, ethnicity, household wealth status, husband’s consumption of alcohol, education level, working status and marriage type. Women that reported to have had their first sex at the age of 18 years or more had lower odds of experiencing this form of domestic violence than women who had their first sex at the age of less than 14 years. The odds of experiencing this form of domestic violence was 66% higher for Lomwe women and 68% higher for Sena, Mang’anja, Nyanja women than Chewa women. Women in the poorer category of the household wealth status variable had 63% higher odds of experiencing this form of domestic violence than those in the poorest category. The odds of experiencing this profile of domestic violence for women that reported that their husbands drink alcohol were nearly seven times higher than the odds for women that reported that their husbands do not drink alcohol. Women with primary education had nearly double the odds of experiencing this type of domestic violence than women with no education. The odds of experiencing this type of domestic violence were 40% higher for women that were currently working than those not working and were three times higher for women in polygamous marriage than in women in monogamous marriage.

## Discussion

This paper examines patterns and correlates of domestic violence against married women in Malawi using cluster analysis and multinomial logistic regression. The explored gender based violence across women of different socio-economic status, education levels, geographical contexts and ethnic background. Five distinct and meaningful clusters/levels of abuse were extracted from the most

recent nationally representative data; no experience of abuse, controlling behaviour, generalised controlling behaviour, moderate physical and emotional abuse and high and complete abuse.

Alcohol consumption and ethnicity were significantly associated with all levels of abuse. The crucial role of alcohol consumption in various types of domestic violence has reported in numerous pieces of literature around the globe (Brecklin & Ullman, 2002; Gilchrist et al., 2003; McKinney, Caetano, Harris, & Ebama, 2009). Alcohol consumption reduces cognitive function, reduces self-control and makes individuals less able to negotiate a non-violent resolution to arguments (Bernardin, 2014; Kim, Kim, & Park, 2016; Room, Babor, & Rehm, 2005). On the other hand, experiencing violence can lead to alcohol abuse whereby individuals may resort to alcohol abuse as a coping mechanism (Wingood, DiClemente, & Raj, 2000) and the relationship between alcohol use and intimate partner violence may at times be moderated by socio-economic status (Greene, Kane, & Tol, 2017).

*We learn from this study that ethnicity is an important geographical factor that is associated with domestic violence in Malawi. Compared to the chewa, the ngonis have lower odds of controlling or physically abusing their wives, while the lomwe, senas, mang'anja and nyanjas's have higher odds of abusing their women. Women from the central region have significantly higher odds of experiencing controlling behaviour compared to women from the northern region. The role of ecological context in influencing behavioural practices/customs was corroborated in an American study after the correlation between race and domestic violence diminished and individual level factors appeared to operate similarly when whites were compared to African Americans in similar contexts (Benson, Wooldredge, B. Thistlethwaite, & Fox, 2004).*

Women's working status was also a popular factor, emerging significant in all four clusters. It is ironic however that although women's employment is an important avenue for increased gender equality, the finding from this study is in agreement with numerous studies have reported that working women are more likely to encounter domestic violence than their non-working counterparts in India and sub Saharan Africa (Ahinkorah, Dickson, & Seidu, 2018; Dalal, 2011; Sohini, 2016). Such a finding is not congruent with the feminist theory (Gelles, 2005) but aligns with the resource theory (K. L. Anderson, 1997). It has been argued that the relationship between women's working status and intimate partner violence may be influenced by whether the partner/husband believes in traditional ideologies of the role of men and women or not (Atkinson, Greenstein, & Lang, 2005). Furthermore, studies that have controlled for endogeneity when modelling the association between intimate partner violence and women's working status have not found a

significant association between women's working status and domestic violence, indicating that women's working status does not necessarily lead to domestic violence (Lenze & Klasen, 2017).

Type of marriage (whether polygamous or monogamous) also emerged as an important factor in three out of the four clusters; generalised controlling behaviour, moderate physical and emotional behaviour and high and complete abuse. The association is strongest for high and complete abuse and lowest in the generalised controlling behaviour. In Malawi, polygamy is common in the northern region where bride price is practised and lineage system is patrilineal. Bride price is the payment made by the groom's family to the bride's family during marriage. It has been indicated that bride price reduces women's status to that of a possession (Gray, 1960). Historically polygamy has been linked to limitation of women's access to land, inheritance and sources of formalised power (Goody, 1973; White & Burton, 1988). Women in polygamous unions are therefore less likely to have a more equal relationship with their partners compared to women in monogamous unions (McCloskey, Williams, & Larsen, 2005). Higher levels of domestic violence in polygamous than monogamous marriages have been reported in Malawi (Bisika, 2008) but a study in Mozambique suggests that senior wives tend to suffer more violence than junior wives and that the level of violence amongst junior wives in polygamous may not significantly differ from women in monogamous marriages or unions (Jansen & Agadjarian, 2016).

Age of the married woman and religion emerged significant in the controlling behaviour and generalised controlled behaviour clusters only. Unsurprisingly younger women are more likely to be controlled than older women. With nearly 50% of girls marrying before adulthood, much higher than the figure for boys, estimated at 8%, most women should be married to older men (NSO-Malawi & ICF\_International, 2017). A strong association has been established between women's age and domestic violence in a global study whereby the majority of women reported to have experienced violence in the first three years of married life, such that the relatively younger women tend to be more affected by violence than older women (Peterman, Bleck, & Palermo, 2015). Similar to the findings of this study, age was not an important factor in physical violence in a sub Saharan study (Andersson et al., 2007).

The finding that Muslim women are more likely to experience controlling behaviour than Christian women may be explained by Islamic teachings that approve control and physical punishment of rebellious wives. Verse 34 of Surah An Nisa states " As to those women on whose part you fear disloyalty and ill-conduct, admonish them (first), (next) do not share beds and last beat (tap) them

lightly; but if they return to obedience, seek not against them means of annoyance : for Allah is Most High, Great (above you all)(Islam.org, 2015). Acceptance and obedience on the part of the wives entail that physical violence may be prevented. Higher levels of violence have been reported among Muslim than Christian women in Iraq in line with findings of this study and in Bangladesh it was found that women that practice Islam have a higher acceptance of spousal violence and less likely to speak against the norm (Al-Tawil, 2012; Biswas , Rahman, Kabir, & Raihan, 2017).

Household wealth status turned out to be a significant predictor of domestic violence in the generalised controlling behaviour and the high and complete abuse clusters, consistent with findings from a study in 18 sub Saharan African countries (Ahinkorah et al., 2018). Interestingly the direction of the relationship between household wealth and domestic violence varies from one place to another(Bamiwuye & Odimegwu, 2014). In a 2014 sub Saharan Africa study on spousal violence, non-poor women from Zambia and Mozambique were more likely to experience violence than the poorer similar to the findings of this study, but in Zimbabwe and Kenya the likelihood of encountering violence was higher for poor women than the richer. On a similar note, this study found that women with primary education were more likely to encounter domestic violence than women with no education. These findings concur with reports that richest women and those with formal education in Burkina Faso have shown a higher likelihood to face psychological pressure from their partners(Pambe', Gnomou, & Kabore', 2013). The behaviour of wealth status and education variables appear to suggest that socio-economic status just like woman's working status may not have a causative relationship with domestic violence in Malawi.

### **Conclusion and Policy Recommendations**

Alcohol consumption, ethnicity and women's working status were consistently associated with all levels of abuse. Age of the married women and religion were only significantly associated with controlling behaviour and generalised controlling behaviour. Alcohol consumption, women's working status and polygamy showed a dose response relationship with domestic violence suggesting that these factors are key to tackling domestic violence in Malawi. The Malawi Government and development partners should consider designing policies and programmes that tackle excessive beer drinking, promotion of the acceptance that women can be bread winners and discouraging the practice of polygamy to curb violence against women in Malawi.
